ABSTRACT

Background: Acne scars are a common problem for those suffering from acne vulgaris. They may result in low self-esteem, especially if located in visible places such as the face. They may even impede normal societal functioning and withdrawal from the environment.

Aim of the study: To investigate the effects of 20% glycolic acid and fractional mesotherapy on the reduction of acne scars.

Material and methods: We used interviews, case analysis and assessment of the effects of glycolic acid treatment and fractional mesotherapy on a 33-year-old female patient who experienced severe phlegmonous acne.

Case report: This 33-year-old female patient was struggling with acne at age 29. Purulent cysts were located on the cheeks and jaws on both sides of her face, leaving deep scars that disturbed everyday functioning. She was alternately given four 20% glycolic acid treatments and four fractional mesotherapy treatments.

Conclusions: The combination of fractional mesotherapy treatments and exfoliation with 20% glycolic acid resulted in significant improvement. Reduced inflammation contributed to decreased acne scars as well as improvement in life quality.

KEYWORDS: scars, AHA, fractional mesotherapy
Aim of the study

This work’s aim is to demonstrate that the cosmetology treatment exfoliation with glycolic acid can synergize with fractional mesotherapy to reduce deep acne scars.

Material and methods

We used interviews, case analysis and assessment of the effects of glycolic acid treatment and fractional mesotherapy on a 33-year-old female patient who experienced severe phlegmonosa acne.

Case report

This 29-year-old female patient exhibited severe acne thought to have been caused by severe long-lasting stress. Pustules on the temples, cheeks, and lower jaws evolved into cysts and fistulas and were associated with great pain. They further hindered normal functioning in everyday life (including work). The patient manually removed them, as acne sufferers often do. In addition, the desire to cover the changes forced the patient to apply a double layer of primer, further hindering skin breathing and clogging skin pores. In 2014, isotretinoin treatment was begun for 8 months, resulting in elimination of acne lesions. However, on the temples, cheeks and jaws scars resulting from cysts, as well as fistulas, remained. After 4 months of taking isotretinoin, the patient’s skin condition improved significantly. At age 33, the patient decided to use combination therapy, consisting of exfoliation with 20% glycolic acid and fractional mesotherapy.

Results

The patient underwent a series of treatments using 20% glycolic acid (pH 2.8) as well as fractional mesotherapy combined with organic silica. Written approval for the procedure, photos and consent of the Bioethically Commission of Public Higher Medical Professional School in Opole were obtained (consent number 14/2018). All contraindications (including pregnancy, lactation, keloid tendencies, anticoagulants, active viral, fungal, bacterial infections, oral steroid therapy, oral isotretinoin, active form of acne) were excluded, minimizing the risk of post-procedural complications. The depth of scars was assessed using the Goodman and Baron scales. The patient was diagnosed with 3rd grade acne according to the above-mentioned scale, meaning that the changes were difficult to cover using makeup (tab. 1). The series included 8 treatments alternating every two weeks for skin regeneration. The first treatment of glycolic acid was applied for 40 seconds, with subsequent skin acid exposures lasting 30 seconds. Glycolic acid 20% pH 2.8 is a strong irritant and sometimes causes bleeding. The acid was always neutralized with a neutralizer to prevent deeper penetration into the skin. After the treatment, a strong regenerating cream was applied, allowing for quicker epidermal reconstruction. After the surgery, the appearance of serous fluid was visible on the treatment day, and scabs and epidermal exfoliation appeared on the second day after treatment, lasting for up to a week. Fractional mesotherapy with organic silica was given alternately with acids every two weeks, and resulted in shallower scars. The treatment consisted of a special device, into which a disposable cartridge with 9 sterile needles was inserted, and a skinprick. Before the facial treatment, an aesthetic preparation was applied while the patient lay for 30–40 minutes (under the occlusion - food foil), which reduced pain. During treatment, bleeding occurred, probably due to growth factor release resulting in collagen remodeling and subsequent improvement of the patient’s skin structure. The scars were reassessed after the treatment series. According to the Goodman–Baron scale, the scars were shallower up to the 2nd grade, implying that the glycolic acid treatments had synergized with fractional mesotherapy to the patient’s benefit.

Discussion

Glycolic acid treatments are widely used and often performed by cosmetologists to reduce acne scars. However, fractional mesotherapy has recently gained in popularity due to its effect on growth factor release by the skin, stimulating and increasing collagen and elastin synthesis, supporting cell health, and stimulating cell growth and division. Combination treatment results in very good shallowing of acne scars. The synergy gives much better results than the performance of the treatments individually. Sharad conducted research

The use of combination therapy with 20% glycolic acid and fractional mesotherapy to reduce acne scars: a case report

on a group of 30 patients with acne scars divided into two groups. The first group was subjected to microcutting for 6 weeks, and the second one to treatments with 35% glycolic acid. They found that both microcutting and exfoliation with acids gave excellent results for the acne scars. Skin structure improved, and acne lesions (scars) were shallower. However, microcutting alone gave better results in making the scars less shallow than a separate acid procedure [10].

Rana et al. investigated the effect of microcutting in combination with 70% glycolic acid and microcutting on a group of 60 patients with acne scars. They showed that the combination of acids and microcutting gave better results than microcutting on its own [11].

Conclusions
The use of combination therapies, in this case, exfoliation with 20% glycolic acid and fractional mesotherapy, resulted in very good and positive therapeutic effects. The decreased inflammation resulted in better and faster regeneration of the skin, flattened acne scars, and improved skin structure, as quantified by the Goodman-Baron scale.
